

AP20R02/PCT/PTO 12 MAY 2006

1 Cancer Diagnosis and Therapy

2

3 Technical Field

4 The invention relates to a novel oncofetal
5 glycoprotein which is expressed in certain tumours,
6 antibodies to the protein, and uses of the
7 antibodies in cancer diagnosis.

8

9 Background Art

10 The cancer phenotype typically displays loss of
11 differentiation, loss of proliferative control and
12 altered cell adhesion molecule expression. Cell
13 surface proteins have been shown to play an
14 important role in cell-cell interactions (eg NCAM),
15 cell-extra-cellular interactions (eg CD44) and cell
16 regulation (eg Notch signaling).

17

18 Some of these cell surface proteins have oncofetal
19 expression profiles and as such have been used as

1 tumour specific diagnostic markers (eg CEA). A
2 further use for antibodies specific for cell
3 surface proteins over expressed in cancer has been
4 in the treatment of cancer by
5 immunotherapy/radioimmunotherapy (eg Herceptin an
6 antibody recognizing HER2).

7

8 Statements of Invention

9 In one aspect, the invention relates to an isolated
10 nucleic acid sequence which comprises a sequence
11 selected from the group consisting of: Sequence ID
12 No.1, Sequence ID No, 2, and Sequence ID No. 3.
13 Typically, the nucleic acid sequence is a DNA
14 sequence. In one embodiment, the isolated nucleic
15 acid sequence consists of a sequence selected from
16 the group consisting of: Sequence ID No. 1, Sequence
17 ID No. 2 and Sequence ID No. 3.

18

19 The invention also relates to an isolated protein
20 encoded by the isolated nucleic acid sequences of
21 the invention, or a fragment or analogue thereof.
22 Typically, the protein is a cell surface
23 glycoprotein. In one preferred embodiment, the
24 isolated protein is an oncofetal protein expressed
25 by an astrocytoma cell. Typically, the protein has a
26 molecular weight of approximately 200kda. In this
27 specification, the term "protein" should be
28 understood as including amino acid sequences which
29 would more generally be referred to a peptides.

30

31 In another aspect, the invention relates to an
32 antibody which binds specifically to the protein of

1 the invention and any other antibody that competes
2 directly or by stearic hindrance therewith for said
3 protein. Typically, the antibody is a monoclonal
4 antibody. In one embodiment, the antibody is a class
5 M immunoglobulin with a kappa-light chain.

6

7 In another aspect, the invention relates to a
8 fragment of the antibody of the invention, which
9 fragment binds specifically to the protein of the
10 invention.

11

12 In another aspect, the invention relates to a method
13 of producing an antibody to a protein comprising:

14

15 - inoculating an animal with a protein according
16 to the invention, wherein the protein elicits an
17 immune response in the animal to produce the
18 antibody; and

19

20 - isolating the antibody from the animal.

21

22 In one embodiment, the animal is inoculated with G-
23 CCM cells of ECACC deposit No. 86022702.

24

25 In a further aspect, the invention relates to a
26 process for producing a hybridoma, comprising the
27 step of inoculating a suitable subject with a
28 protein according to the invention, or an antigenic
29 fragment thereof, and fusing cells from the subject
30 with a myeloma cell to produce the hybridoma.

31 Typically, the subject is inoculated with G-CCM
32 cells of ECACC deposit No. 86022702.

1

2 In a further aspect, the invention relates to a
3 hybridoma cell obtainable according to the above
4 process. In one embodiment, the invention relates to
5 a hybridoma cell of, or derived from, ECACC Deposit
6 No. 03073001.

7

8 A deposit of hybridoma cells according to the
9 invention was made at the European Collection of
10 Cell Cultures on 30 July 2003 and accorded the
11 accession number ECACC 03073001.

12

13 In another aspect, the invention relates to a
14 monoclonal antibody obtainable from a hybridoma cell
15 of, or derived from, ECACC Deposit No. 03073001.

16

17 The invention also relates to a method of detecting
18 an astrocytoma cell in a sample of human cells,
19 which method comprises the step of contacting the
20 cell sample with an antibody of the invention, or a
21 fragment thereof, and detecting those cells which
22 have bound the antibody or fragment, wherein binding
23 of the antibody or the fragment to a cell is
24 indicative of an astrocytoma cell. Typically, the
25 antibody is a monoclonal antibody of the invention.

26

27 The invention also relates to a method of detecting
28 a primary breast carcinoma cell in a sample of human
29 cells, which method comprises the step of contacting
30 the cell sample with an antibody of the invention,
31 or a fragment thereof, and detecting those cells
32 which have bound the antibody or fragment, wherein

1 binding of the antibody or the fragment to a cell is
2 indicative of a primary breast carcinoma cell.
3 Typically, the antibody is a monoclonal antibody of
4 the invention.

5

6 The invention also relates to a diagnostic kit for
7 diagnosing the presence of a cell selected from the
8 group consisting of: astrocytoma cells; malignant
9 melanoma secondary tumour cells; and primary breast
10 carcinoma cells, the kit comprising an antibody
11 according to the invention, or a fragment thereof.
12 Typically, the antibody is a monoclonal antibody of
13 the invention. In one embodiment, the antibody of
14 the invention comprises a detectable label.
15 Alternatively, the kit comprises a secondary
16 antibody which specifically binds the antibody of
17 the invention, which secondary antibody comprises a
18 detectable label.

19

20 The invention also relates to a biological targeting
21 device comprising an antibody, typically a
22 monoclonal antibody, of the invention, or a fragment
23 thereof, and a therapeutic ligand.

24

25 The invention also relates to a therapeutic antibody
26 comprising an antibody, typically a monoclonal
27 antibody, of the invention, or a fragment thereof.

28

29 The invention also relates to a method of treating
30 cancer in an individual by inducing apoptosis in
31 cells in the individual which express a protein of
32 the invention, which method comprises a step of

1 treating an individual with an antibody of the
2 invention, or a fragment thereof. Typically, the
3 antibody is a monoclonal antibody. In one
4 embodiment, the cancer is selected from the group
5 consisting of: malignant astrocytomas ; malignant
6 melanoma secondary tumours; and primary breast
7 carcinomas. Typically, the antibody is humanised.

8

9 The invention also relates to a polynucleotide which
10 is anti-sense to at least a portion of an isolated
11 nucleic acid sequence of the invention. Typically,
12 the polynucleotide is anti-sense to all or part of a
13 transcription initiator site of the isolated nucleic
14 acid sequence of the invention. In one embodiment,
15 the anti-sense polynucleotide comprises, or consists
16 of, a sequence of Sequence ID No. 4.

17

18 The invention also relates to a method of treating
19 cancer in an individual by inducing apoptosis in
20 cells in the individual which express a protein of
21 the invention, which method comprises a step of
22 treating an individual with an anti-sense
23 polynucleotide of the invention. In one embodiment,
24 the cancer is selected from the group consisting of:
25 malignant astrocytomas; malignant melanoma secondary
26 tumours; and primary breast carcinomas. Methods of
27 delivery of anti-sense polynucleotides will be well-
28 known to those skilled in the art of gene therapy.

29

30 The monoclonal antibodies of the invention may be
31 the complete antibodies described herein, or
32 fragments thereof. That is, they may be any fragment

1 of a monoclonal antibody of the invention that
2 specifically recognises the protein of the
3 invention. Such fragments include Fab, F(ab')₂,
4 Fab', etc. These fragments can be prepared by
5 digestion with an enzyme such as papain, pepsin,
6 ficin, or the like. The properties of the obtained
7 fragments can be confirmed in the same manner as
8 described herein.

9
10 The principle reason for the poor prognosis
11 associated with malignant astrocytomas is recurrence
12 due to invasion of surrounding brain parenchyma by
13 tumour cells with an invasive phenotype. This
14 phenotype displays loss of differentiation,
15 secretion of proteases and altered cell adhesion
16 molecule expression. As part of an investigation
17 into the mechanisms of astrocytoma invasion,
18 monoclonal antibodies (Mab) were raised against cell
19 surface proteins expressed by an anaplastic
20 astrocytoma cell line (G-CCM). One of the
21 antibodies produced (MQ1 Mab) recognizes a
22 previously undescribed cell surface glycoprotein
23 (MQ1). In vitro MQ1 protein expression was found on
24 astrocytomas and fetal astrocytes, with the level of
25 expression increasing with astrocytoma malignancy
26 and decreasing with fetal astrocyte maturity.
27 Immunohistochemistry on histologically normal and
28 neoplastic brain tissue demonstrated that MQ1
29 protein expression is restricted to astrocytomas
30 (n=52). Other primary brain tumours tested
31 (oligodendrogliomas, neurinomas, PNET, and
32 medulloblastomas) and normal brain cells, including

1 neurons, oligodendrocytes and endothelial cells were
2 MQ1 negative, thus indicating that the MQ1 proteins
3 have the expression pattern of oncofetal proteins.
4 Similarly a study looking at primary breast
5 carcinomas found 60% were MQ1 positive (n=228).
6 Surrounding normal tissue, fibrocystic disease and
7 fibroadenoma tissue were MQ1 negative. Malignant
8 melanoma secondary tumours to the brain were also
9 found to be strongly MQ1 positive.

10

11 A cDNA expression library was synthesized from G-CCM
12 mRNA and screened with the MQ1 antibody. Two
13 positive clones were isolated (Sequence ID No.s 1
14 and 2) and sequencing data demonstrated that both
15 have a high degree of homology with Jagged1, a human
16 Notch ligand which plays a role in differentiation
17 and determination of cell fate. The library was
18 rescreened with probes generated from the positive
19 clones and further homologous transcripts were
20 isolated including a possible Jagged1 splice variant
21 (Sequence ID No. 3). Northern blotting for a range
22 of cell lines with these probes revealed the
23 presence of two transcripts (approximately 3.5kb &
24 5.0kb). Subsequent protein studies
25 (immunocytochemistry, immunoblotting and co-
26 immunoprecipitation) indicate that the MQ1 protein
27 has a high degree of homology with, but is not
28 identical to, Jagged1.

29

30 This investigation has identified a novel oncofetal
31 glycoprotein with homology to Jagged1. Its tumour
32 specificity together with its potential role in

1 regulating cellular differentiation /apoptosis
2 suggest that it may be a valuable prognostic marker
3 and therapeutic target.

4

5 The invention will be more clearly understood from
6 the following description of some embodiments
7 thereof, given by way of example only, with
8 reference to the following Figures in which:

9

10 Fig.1A illustrates confocal microscopy of live G-CCM
11 cells immunolabelled with MQ1 showing recognition of
12 a cell surface epitope;

13

14 Fig. 1B illustrates confocal microscopy of
15 permeabilized G-CCM cells immunolabelled with MQ1
16 showing recognition of an intracellular epitope and
17 localisation of the antigen at areas of cell contact
18 on the cell surface;

19

20 Fig 2 shows a comparison of MQ1 expression, by
21 immunocytochemistry and flow cytometry, on a range
22 of fetal astrocyte cultures and astrocytoma cell
23 lines. A-C show immunocytochemistry on live cells of
24 a grade IV, grade III and 16 week gestation fetal
25 astrocytes respectively. D-F show the corresponding
26 flow analysis with the same cells with the level of
27 MQ1 surface expression estimated as mean channel
28 fluorescence. G shows the results of the flow
29 analysis plotted as a graph. This demonstrates an
30 inverse correlation of cell surface MQ1 protein
31 expression with fetal astrocyte maturity and
32 correlation with astrocytoma grade;

1

2 Fig.3 shows immunohistochemistry displaying diffuse
3 MQ1 positivity throughout A) Grade I astrocytomas B)
4 Grade II astrocytomas C) Grade III astrocytomas & D)
5 focal positivity in grade IV astrocytoma cells
6 palisading an area of necrosis;

7

8 Fig.4 shows MQ1 immunocytochemistry showing A)
9 strong MQ1 positivity at the tumour front B) strong
10 MQ1 positivity in reactive astrocytes in adjacent
11 tissue C) GFAP positivity in reactive MS tissue D)
12 MQ1 negative reactive MS tissue;

13

14 Fig. 5 shows MQ1 immunohistochemistry of breast
15 carcinoma tissue showing A) strong MQ1 positivity in
16 invasive ductal carcinoma cells surrounded by MQ1
17 negative stroma B) strong MQ1 positivity in lobular
18 carcinoma surrounded by MQ1 negative stroma;

19

20 Fig.6 shows MQ1 immunocytochemistry of G-CCM cells
21 treated with (A) 0.1 μ m control oligo (B) 0.5 μ m
22 control oligo (C) 1.0 μ m control oligo (D) 0.1 μ m
23 anti-sense MQ1 oligo (E) 0.5 μ m anti-sense MQ1 oligo
24 and (F) 1.0 μ m antisense oligo, showing that MQ1
25 anti-sense oligo knocks out MQ1 protein expression
26 at concentrations of 0.5 and 1.0 μ m;

27

28 Fig. 7 shows an immunoblot indicating Parp cleavage
29 of oligo-treated G-CCM cells;

30

31 Fig. 8 shows immunocytochemistry (ICC) detection of
32 cleaved Caspase 3 following oligo treatment1; and

1

2 Fig. 9 shows G-CCM cells labelled with MQ1 antibody
3 by ICC, 24 hours post-treatment with control and
4 anti-sense oligonucleotides in which:

5

6 (A) control oligo 0.1 μ M

7 (B) control oligo 0.5 μ M

8 (C) control oligo 1.0 μ M

9 (D) Anti-sense oligo 0.1 μ M

10 (E) Anti-sense oligo 0.5 μ M

11 (F) Anti-sense oligo 0.1 μ M

12

13 MATERIALS AND METHODS

14

15 Materials

16

17 All cell culture reagents were obtained from Gibco
18 BRL (Paisley, UK) with the exception of the
19 hypoxanthine, aminopterin and thymidine (HAT) and
20 the hypoxanthine and thymidine (HT) that were
21 obtained from Sigma (Poole, Dorset, UK). The
22 secondary and negative control antibodies were
23 supplied by Dako (Bucks, UK). The PARP and Caspase3
24 antibodies were purchased from Sigma (Poole, Dorset,
25 UK) and the Protein-A Sepharose CL4B from Pharmacia
26 Biotech (Herts, UK). PTO linked oligonucleotides
27 were obtained from MWG-Biotech (Germany).

28

29 Cell culture

30

31 The CB109 cell line was established from a
32 glioblastoma multiforme [6] and was a gift from Dr

1 Claude Chauzy (Centre Henri Becquerel, Rouen,
2 France). The G-CCM cell line was derived from a
3 human anaplastic astrocytoma and was a gift from Dr
4 Ian Freshney (Department of Clinical Oncology,
5 University of Glasgow, UK). The G-CCM cell line is
6 commercially available from the European Collection
7 of Cell Cultures under Deposit No 86022702. The
8 fetal astrocyte cell cultures were a gift from Ms
9 Kim Martin (Department of Neuropathology, Institute
10 of Psychiatry, London, UK). The C6 cell line,
11 derived from a rat glioma, was obtained from Flow
12 Laboratories (Scotland, UK). The skin fibroblast
13 cell culture was initiated in our laboratory from a
14 surgical specimen obtained from the Neurological
15 Unit (Royal Victoria Hospital, Belfast, UK). The
16 remaining glioma cell lines were initiated in our
17 laboratory from surgical specimens received from the
18 Neurosurgical Unit (Royal Victoria Hospital,
19 Belfast, UK) and were used experimentally after 5-10
20 passages. Tumour grading follows the World Health
21 Organisation classification. Cell lines were
22 incubated at 37°C/5% CO₂ in Dulbecco's modified
23 Eagle's medium (DMEM) containing 2mM glutamine, 10%
24 fetal calf serum (FCS), and phenol red. All cell
25 lines were tested for mycoplasma using Hoechst 33258
26 fluorescent dye and were found to be negative.

27

28 Monoclonal antibody production

29

30 Mabs were produced utilizing a standardized protocol
31 designed to promote a rapid predominantly IgG
32 response. In brief, a BALB/c mouse was inoculated

1 intra-peritoneally with 5×10^6 G-CCM cells in 1ml of
2 Freund's complete adjuvant. Similar doses
3 emulsified in Freund's incomplete adjuvant were
4 administered 14 and 28 days later to boost the
5 immune response. Four days after the final booster
6 inoculation the mouse was killed, its spleen
7 aseptically removed and the splenocytes induced to
8 fuse with NSO myeloma cells (at a ratio 5:1) using
9 polyethylene glycol. The resulting fusion products
10 were suspended in a selective, HAT-supplemented,
11 growth medium (RPMI-1640 medium containing 10mM L-
12 glutamine, 1% sodium pyruvate, 100 iu/ml penicillin,
13 100µg/ml streptomycin and 20% Myoclone FCS) and
14 seeded into 96-well plates. The medium, from the
15 viable hybridomas produced, was screened by indirect
16 immunofluorescence against live and acetone-fixed G-
17 CCM cells. Those showing specific recognition were
18 recloned three times, to ensure monospecificity, in
19 HT-supplemented growth medium and stored in liquid
20 nitrogen. The hybridoma cell line MQ-1, which
21 produced an antibody recognizing a cell surface
22 antigen was propagated as an ascitic tumour in
23 BALB/c mice previously immunosuppressed with
24 Pristane. The ascitic fluids were collected,
25 centrifuged and frozen at -20°C until use.

26

27 The positively labelling Mabs were isotyped for
28 their class and light chains using a monoclonal
29 antibody isotyping kit.

30

31

32

1 Immunofluorescence

2

3 Hybridoma medium (neat) or ascites fluid (diluted
4 1:200 in PBS) was incubated with living cells, grown
5 to 90% confluence on coverslips, for 40 min at room
6 temperature (RT). After washing, the cells were
7 fixed in acetone at -20°C for 10 min followed by
8 rehydration in PBS and incubation with an FITC-
9 conjugated rabbit antimouse antibody (FITC-RAM) for
10 30 min at RT. After two further washes the cells
11 were mounted on a glass slide, in a drop of
12 Citifluor, and examined using a Zeiss
13 immunofluorescence microscope or a Biorad confocal
14 microscope. Incubations in PBS without primary
15 antibody were used as negative controls. The
16 fluorescent labelling of positive cells was
17 subjectively rated from low intensity (+) to high
18 intensity (++++).

19

20 Flow Cytometry

21

22 A preliminary study (results not shown) comparing
23 the expression of MQ-1 protein on cells removed
24 enzymatically (trypsin) and non-enzymatically (0.53
25 mM EDTA in PBS) from culture flasks, revealed that
26 the MQ1 protein epitope was trypsin-resistant.

27

28 Cultured cells were removed from the flasks by
29 trypsinization, counted and aliquoted into
30 centrifuge tubes at a concentration of 5×10^5 cells
31 per tube. Triplicate samples were incubated in
32 excess ascitic fluid in 200 μ l of serum free medium

1 containing 1% bovine serum albumin (SFM/BSA) for 40
2 min at RT with gentle agitation. Following 2
3 washes in SFM the cells were incubated in an FITC-
4 RAM antibody for 30 min at RT with gentle
5 agitation. The cells were then washed twice in SFM
6 and fixed in PBS containing 1% para-formaldehyde.
7 The samples were analysed within 48 hr of fixation,
8 using a Coulter EPICS Elite flow cytometer.
9 Negative controls were incubated with an antibody
10 raised against *Aspergillus niger* glucose oxidase, an
11 enzyme not present or inducible in mammalian cells.
12 The consistency of the mean channel fluorescence
13 measurements between sample batches was checked
14 using EPICS Immuno-Brite standards.

15

16 Immunohistochemistry

17

18 On receipt the tissue was fixed in 10% formalin
19 prior to routine embedding in paraffin wax using a
20 Tissue Tex VIP (Miles Scientific) automated
21 processor. The paraffin blocks were sectioned at a
22 thickness of 6mm and mounted onto 3-
23 aminopropyltriethoxysilane-coated slides. The
24 tissue sections for indirect immunohistochemistry
25 were processed using an avidin-biotin peroxidase
26 complex (ABC) method. The tissue was dewaxed in
27 xylene and rehydrated before endogenous peroxidase
28 activity was blocked by a 10min incubation in 3%
29 H₂O₂ in methanol at room temperature (RT). To
30 counter antigen masking, due to the formalin
31 fixation, the tissue was pretreated with microwave
32 irradiation to promote antigen retrieval. The

1 sections were washed in distilled water and placed
2 in 0.01M Tri-Na citrate pH7.8 and irradiated in a
3 Miele microwave oven for 6min (2x3min) at 450W (the
4 optimal time and intensity of irradiation was
5 determined from preliminary studies). After
6 incubation in PBS containing 5% normal rabbit serum
7 for 10min at RT the sections were incubated in MQ1
8 ascites (diluted 1:50 in PBS) at 4C overnight.
9 Following 2x5min washes in PBS the sections were
10 incubated in biotinylated rabbit anti-mouse IgM
11 diluted 1:400 in PBS for 40min at RT. After further
12 washes in PBS, a streptavidin-biotin complex linked
13 to peroxidase was added to the sections and
14 incubated for 40min at RT. The peroxidase reaction
15 was developed in 0.1% diaminobenzidine in PBS
16 activated with 1% H₂O₂. After washing in water, the
17 sections were counterstained in haematoxylin,
18 dehydrated through graded alcohols, cleared in
19 xylene and mounted in DPX. In addition to negative
20 controls, incubated with a primary antibody raised
21 against *Aspergillus niger* glucose oxidase, positive
22 controls of histologically normal brain and
23 astrocytoma tissue were included with every batch.
24 cDNA Expression Library and screening.

13
14 RESULTS

15
16 Antibody Production

17
18 The fusion resulted in the production of five viable
19 antibody secreting hybridomas which screened
20 positively by immunofluorescence microscopy on
21 acetone fixed G-CCM cells. Of these, one (hybridoma
22 MQ1) was found to secrete an antibody which was
23 isotypd as a class M immunoglobulin with a kappa-
24 light chain. This antibody recognizes a cell
25 surface epitope, showing punctate labelling, on live
26 G-CCM cells. Further examination by confocal
27 microscopy confirmed the cell surface labelling of
28 live G-CCM cells and revealed the presence of an
29 intra-cellular epitope in permeabilized cells
30 (Figure 1A&B). In addition examination of the
31 permeabilized cells demonstrated localisation of
32 labelling at focal adhesion points on the cell

1 surface.

2

3 Immunocytochemistry

4

5 A range of cell lines was examined by indirect
6 immunofluorescence for the presence of the MQ-1
7 antigen
8 (Table 1).

1 Table 1. Indirect immunofluorescence on a range of
2 live cell lines and cell cultures with MQ1 antibody.

3

4 The results show that the human skin fibroblasts and
5 the C6, rat glioma, cell lines do not express the
6 antigen. The fetal astrocytes and glioma cell lines
7 were positive with the exception of two cell lines
8 (CB109 and NP670/92) derived from glioblastomas
9 multiforme. Under subjective microscopic analysis
10 there appeared to be a variation in labelling
11 intensity between the positive cell lines. The high
12 grade gliomas had a higher labelling intensity than
13 low grade gliomas and fetal astrocytes. This was
14 confirmed by flow cytometry (Figure 2). The results
15 show a progressive increase in MQ-1 antigen
16 expression, as estimated by the mean channel
17 fluorescence, from low to high grade astrocytomas,
18 the expression on grade IV astrocytomas being more
19 than double that of grade I astrocytomas. The fetal
20 astrocytes showed a lower expression than the
21 astrocytoma cell lines, that halved from fetal
22 astrocytes of 12 weeks gestation to 16 weeks
23 gestation.

24

25 Immunohistochemistry

26

27 The results of the immunohistochemical study on
28 primary brain tumours are summarized in Table 2.

29

Table 2

Tumour	# Biopsies	MQ1 positivity
Astrocytomas	30	29/30
Neurinoma	3	0/3
Oligodendroglioma	3	0/3
Medulloblastoma	3	0/3
PNET	3	0/3

1 Table 2 Immunohistochemical analysis of MQ1 immuno-
 2 labelling of a range of Primary Brain Tumours
 3 showing that of the tumour tissue tested only
 4 astrocytomas displayed MQ1 positivity.
 5
 6 The results show that of all the primary brain
 7 tumours tested (oligodendrogliomas, PNET etc) only
 8 astrocytomas were MQ1 positive.
 9 All pilocytic (grade I) astrocytomas showed a
 10 similar staining pattern. There was strong cellular
 11 immunostaining of MQ1 proteins which extended to the
 12 cellular processes of bipolar cells (Fig3A). The
 13 immunopositive cells stood out prominently against a
 14 loosely arranged less cellular stroma.
 15 The astrocytomas (grade II) and anaplastic (grade
 16 III) astrocytomas revealed a diffuse
 17 immunopositivity and the staining pattern was
 18 similar in all (Fig 3B&C). There was variation in
 19 the staining pattern of glioblastomas. Out of 16
 20 glioblastomas tested, 1 was unreactive revealing no
 21 MQ1 protein expression whereas 14 showed focal
 22 positivity and one diffuse immunostaining (Fig 3D).
 23 Focal positivity was observed as clusters or groups

1 of positive cells surrounded by unreactive areas.
2 Tumour cells palisading around areas of necrosis, a
3 characteristic feature of glioblastomas also revealed
4 focal positivity. However tumour giant cells,
5 bizarre cells and clusters of proliferating
6 endothelial cells were negative for MQ1 protein
7 expression. The oligodendroglial cells were
8 negative. Within adjacent grey matter the neurones
9 did not show immunolabelling for the MQ1 proteins.
10 The endothelial cells lining small and large blood
11 vessels in and around tumours of all grades showed
12 no MQ1 protein expression. There was no
13 immunolabelling of lymphocytes in the perivascular
14 spaces. The infiltrating edge of the tumours and
15 the adjacent glial areas showed prominent labelling
16 of large reactive astrocytes (Fig 4 A&B)). Such
17 cells revealed multiple processes. However this MQ1
18 positivity in reactive astrocytes was only found
19 surrounding MQ1 positive tumours, other reactive
20 tissue such as MS tissue that shows prominent
21 reactive astrocytes when labeled for GFAP (FIG 4C)
22 displayed no MQ1 positivity in the 10 biopsies
23 tested (Fig 4D).
24 In non-CNS tissue tested malignant melanoma and
25 breast 20 to the brain were found to express the MQ1
26 proteins (Table 3).

Table 3

Tissue	# Biopsies	MQ1 Positivity
Breast 20 (brain)	3	3/3
Breast 10	228	137/228

Fibroadenoma	5	0/5
Fibrocystic Disease	5	0/5
M.Melanoma2o (brain)	4	4/4

1

2 Table 3 Immunohistochemical MQ1 immunolabelling of a
3 range of non-CNS tumours, showing MQ1 positivity in
4 60% of primary breast tumours and no positivity in
5 fibrocystic disease and fibroadenomas that are non-
6 malignant breast conditions.

7

8 Of the primary breast tumours tested 137/228 were
9 MQ1 positive while fibrocystic disease and
10 fibroadenoma tissues, both premalignant conditions
11 displayed no MQ1 positivity. Figure5 shows strong
12 MQ1 positivity in invasive ductal carcinoma cells
13 and lobular carcinoma cells surrounded by MQ1
14 negative stroma.

15

16 Isolation of MQ-1 Clones

17

18 Screening of a cDNA expression library (from G-CCM
19 mRNA) with the MQ1 antibody identified two clones
20 with significant homology to the Jagged 1 protein
21 (Sequence ID No's 1 and 2).

22

23 Antisense Treatment Protocol

24

25 Antisense Oligonucleotide

26 5'-tgg gga acg cat cgc tgc-3' (Sequence ID No. 4)

27

28 Antisense Control Oligonucleotide

29 5'-tgg gga ccg cat cgc tgc-3' (Sequence ID No. 5)

1
2 The PTO linked antisense oligonucleotide was
3 designed against the transcription initiation site
4 and kozac sequence at the beginning of the Jagged1
5 gene (Accession number AF028593). The control
6 oilgonucleotide was the same 18 mer with one base
7 changed (therefore being the tightest control
8 possible to generate). Both oligonucleotides were
9 synthesized by MWG Biotech. For colony count assays
10 G-CCM cells were seeded out into 24well plates at
11 50,000 cells/well. The cells were incubated for
12 24hrs in growth medium and then washed with serum
13 free medium (SFM). The cells were then either
14 treated with lipofectin (Invitrogen Life
15 Technologies) alone following the standard protocol
16 (at 5µl/ml) or lipofectin with the antisense and
17 antisense control oligonucleotides at a range of
18 concentrations (0.1, 0.5 and 1.0 µM) for 16hrs.
19 Following treatment the cells were washed twice with
20 SFM and then incubated in growth medium for 24 and
21 48hrs. The results (Figure 6) show that treatment
22 with the antisense oligonucleotide at concentrations
23 of 0.5 and 1.0 µM reduced the tumour cell population
24 when compared to the control oligonucleotide and
25 lipofectin alone treatment. To assess whether this
26 was due to the induction of apoptosis similarly
27 treated cells were harvested for their protein and
28 examined for Parp cleavage (an indicator of
29 apoptosis) by immunoblotting. The results (Figure
30 7) clearly show a reduction in the level of Parp at
31 0.5 and 1.0µM antisense oligonucleotide treatment
32 when compared to control oligonucleotide and

1 lipofectin alone treatment. Thus indicating that
2 the antisense oligonucleotide treatment induces
3 apoptosis in the G-CCM cells. To confirm this,
4 treated G-CCM cells were also examined for the
5 presence of cleaved Caspase 3 (another indicator of
6 apoptosis) by immunocytochemistry. The results
7 (Figure 8) show that G-CCM cells treated with 1.0 μ M
8 displayed caspase 3 cleavage thus indicating that
9 apoptosis was being induced. To demonstrate that
10 these effects were due to the knocking out of the
11 MQ1 proteins by the antisense oligonucleotides,
12 treated cells were examined for the presence of the
13 MQ1 proteins by immunocytochemistry with the MQ1
14 antibody. The results (Figure 9) show that the
15 expression levels of the MQ1 proteins is reduced by
16 antisense oligonucleotide treatment when compared to
17 the control oligonucleotide.

18

19 The invention described herein has potential uses as
20 a:

21

22 Diagnostic Tool- The antibody clearly distinguishes
23 astrocytomas from other primary brain tumours,
24 normal cells and reactive gliosis. In addition it
25 recognizes 60% of primary breast tumours tested.

26

27 Targeting Device- The specificity of the antibody
28 means it can be used as a targeting device such as
29 in radioimmunotherapy.

30

31 Therapeutic Target- The antibody itself can be used
32 as a therapeutic agent by blocking out signaling

1 through the MQ1/Notch pathway thus inducing
2 apoptosis in astrocytoma cells.

3

4 The invention is not limited to the embodiments
5 hereinbefore described which may be varied without
6 departing from the spirit of the invention.
